

Python tutorials

Sunday, 13 February 2022 9:06 pm

Questions :

(1) if `__name__ == "__main__"`:

#	Name	Description
1	Intro	<p>Python-programming language. Created by Guido van Rossum, and released in 1991. Used for web development(server side), s/w development, maths and scripting.</p> <p>Why python:</p> <ul style="list-style-type: none">- works on different platform (Windows, Linux, Mac, Rasberry, Pi, etc)- simple syntax, similar to English language- fewer lines of code and runs on an interpreter system (prototyping can be very quick).- python can be treated in procedural way, an object-oriented way or a functional way.
2	HelloWorld Program	<pre>def print_hi(): print("Hello World!!!") if __name__ == "__main__": print_hi()</pre>
3	Command line options	<p>--python version python --version or py version</p> <p>--running python python <python file name></p> <p>--exit command line exit()</p>
4	Syntax/Indentation/Variable	<p>Syntax: syntax can be executed by writing directly in the Command Line (Or), by executing python script e.g. switch to the python exe location > print("Hello World") > python helloWorld.py</p> <p>Indentation: Indentation refers to the spaces at the beginning of a code line. indentation uses to indicate the block of code. if 5< 2: print("condition satisfied")</p> <p>Variable: variables are created when you assign a value to it. e.g. x = 5; y =" Hello World"</p>
5	Comment Single/Multi line	<ol style="list-style-type: none">1. Using #2. Using triple quotes
6	Variables	<ol style="list-style-type: none">1. No declaration required for variable.2. Variables are created the moment we first assign a value to it.3. single/double quotes -> string variables can be declared either by single or double quotes.4. case-sensitive - variable names are case sensitive. <p>----</p> <p>Variable Name: must start with letter or "_". it can contain only alpha-numeric charracters and "_". its case sensitive.</p>

```

Multi Words Variable Names:
Camel Case :
myVariableName = "John "
Pascal Case
MyVariableName = "John"
Snake Case
my_variable_name = "John"

---

#Many values to multiple variables
x, y, z = "Orange", "Apple", "Banana"
print ( "x = " + x + " : y = " + y + " : z = " + z )

#same value to multiple variable
x=y=z="same value"
print ( "x = " + x + " : y = " + y + " : z = " + z )

#Unpack collections
fruits = ["Apple", "Orange", "Banana"]

a,b,c = fruits
print ( "a = " + a + " : b = " + b + " : c = " + c )

#output variables
print("value of a is " + a )
print ("a + b = " + a+b) #same type of variables can be added.
#but string and int CAN NOT be added.

#global variable
g_var = ""
def sample_fun():
    g_var = "global variable value"

def sample_fun2():
    global g_var2;
    g_var2 = "global variable value 2"

sample_fun()
sample_fun2()

print("global variable example")
print(g_var)
print(g_var2)

```

Data types

Text Type:

Numeric Types:

Sequence Types:

Mapping Type:

Set Types:

Boolean Type:

Binary Types:

(e.g)

x = "Hello World"	str
x = 20	int
x = 20.5	float

str

int, float, complex

list, tuple, range

dict

set, frozenset

bool

bytes, bytearray, memoryview

x = 1j	complex
x = ["apple", "banana", "cherry"]	list
x = ("apple", "banana", "cherry")	tuple
x = range(6)	range
x = {"name" : "John", "age" : 36}	dict
x = {"apple", "banana", "cherry"}	set
x = frozenset({"apple", "banana", "cherry"})	frozenset
x = True	bool
x = b"Hello"	bytes
x = bytearray(5)	bytearray
x = memoryview(bytes(5))	memoryview

8	casting	<p>int() - constructs an integer number from an integer literal, a float literal (by removing all decimals), or a string literal (providing the string represents a whole number)</p> <p>float() - constructs a float number from an integer literal, a float literal or a string literal (providing the string represents a float or an integer)</p> <p>str() - constructs a string from a wide variety of data types, including strings, integer literals and float literals</p> <p>List()</p> <p>Tuple()</p>																							
9	String (all functions are not implemented)	<table><thead><tr><th>Method</th><th>Description</th></tr></thead><tbody><tr><td>capitalize()</td><td>Converts the first character to upper case</td></tr><tr><td>casefold()</td><td>Converts string into lower case</td></tr><tr><td>center()</td><td>Returns a centered string</td></tr><tr><td>count()</td><td>Returns the number of times a specified value occurs in a string</td></tr><tr><td>encode()</td><td>Returns an encoded version of the string</td></tr><tr><td>endswith()</td><td>Returns true if the string ends with the specified value</td></tr><tr><td>expandtabs()</td><td>Sets the tab size of the string</td></tr><tr><td>find()</td><td>Searches the string for a specified value and returns the position of where it was found</td></tr><tr><td>format()</td><td>Formats specified values in a string</td></tr><tr><td>format map</td><td>Formats specified values in a string</td></tr></tbody></table>	Method	Description	capitalize()	Converts the first character to upper case	casefold()	Converts string into lower case	center()	Returns a centered string	count()	Returns the number of times a specified value occurs in a string	encode()	Returns an encoded version of the string	endswith()	Returns true if the string ends with the specified value	expandtabs()	Sets the tab size of the string	find()	Searches the string for a specified value and returns the position of where it was found	format()	Formats specified values in a string	format map	Formats specified values in a string	
Method	Description																								
capitalize()	Converts the first character to upper case																								
casefold()	Converts string into lower case																								
center()	Returns a centered string																								
count()	Returns the number of times a specified value occurs in a string																								
encode()	Returns an encoded version of the string																								
endswith()	Returns true if the string ends with the specified value																								
expandtabs()	Sets the tab size of the string																								
find()	Searches the string for a specified value and returns the position of where it was found																								
format()	Formats specified values in a string																								
format map	Formats specified values in a string																								

()	
index()	Searches the string for a specified value and returns the position of where it was found
isalnum()	Returns True if all characters in the string are alphanumeric
isalpha()	Returns True if all characters in the string are in the alphabet
isdecimal()	Returns True if all characters in the string are decimals
isdigit()	Returns True if all characters in the string are digits
isidentifier()	Returns True if the string is an identifier
islower()	Returns True if all characters in the string are lower case
isnumeric()	Returns True if all characters in the string are numeric
isprintable()	Returns True if all characters in the string are printable
isspace()	Returns True if all characters in the string are whitespaces
istitle()	Returns True if the string follows the rules of a title
isupper()	Returns True if all characters in the string are upper case
join()	Joins the elements of an iterable to the end of the string
ljust()	Returns a left justified version of the string
lower()	Converts a string into lower case
lstrip()	Returns a left trim version of the string
maketrans()	Returns a translation table to be used in translations
partition()	Returns a tuple where the string is parted into three parts
replace()	Returns a string where a specified value is replaced with a specified value
rfind()	Searches the string for a specified value and returns the last position of where it was found
rindex()	Searches the string for a specified value and returns the last position of where it was found
rjust()	Returns a right justified version of the string
rpartition()	Returns a tuple where the string is parted into three parts
rsplit()	Splits the string at the specified separator, and returns a list
rstrip()	Returns a right trim version of the string
split()	Splits the string at the specified separator, and returns a list
splitlines()	Splits the string at line breaks and returns a list
startswith()	Returns true if the string starts with the specified value
strip()	Returns a trimmed version of the string
swapcase()	Swaps cases, lower case becomes upper case and vice versa
title()	Converts the first character of each word to upper case
translate()	Returns a translated string
upper()	Converts a string into upper case
zfill()	Fills the string with a specified number of 0 values at the beginning

10

Operators

Arithmetic Operators

Operator	Name	Example
+	Addition	x + y
-	Subtraction	x - y
*	Multiplication	x * y
/	Division	x / y
%	Modulus	x % y

**	Exponentiation	x ** y
//	Floor division	x // y

Assignment Operators

Operator	Example	Same As	
=	x = 5	x = 5	
+=	x += 3	x = x + 3	
-=	x -= 3	x = x - 3	
*=	x *= 3	x = x * 3	
/=	x /= 3	x = x / 3	
%=	x %= 3	x = x % 3	
//=	x //= 3	x = x // 3	
**=	x **= 3	x = x ** 3	
&=	x &= 3	x = x & 3	
=	x = 3	x = x 3	
^=	x ^= 3	x = x ^ 3	Exclusive OR
>>=	x >>= 3	x = x >> 3	
<<=	x <<= 3	x = x << 3	

Comparison Operators

Operator	Name	Example
==	Equal	x == y
!=	Not equal	x != y
>	Greater than	x > y
<	Less than	x < y
>=	Greater than or equal to	x >= y
<=	Less than or equal to	x <= y

Logical Operators

Operator	Description	Example
and	Returns True if both statements are true	x < 5 and x < 10
or	Returns True if one of the statements is true	x < 5 or x < 4
not	Reverse the result, returns False if the result is true	not(x < 5 and x < 10)

Identity Operators

Operator	Description	Example
is	Returns True if both variables are the same object	x is y
is not	Returns True if both variables are not the same object	x is not y

Membership Operators

Operator	Description	Example
in	Returns True if a sequence with the specified value is present in the object	x in y
not in	Returns True if a sequence with the specified value is not present in the object	

Bitwise Operators

Operator	Name	Description

&	AND	Sets each bit to 1 if both bits are 1
	OR	Sets each bit to 1 if one of two bits is 1
^	XOR	Sets each bit to 1 if only one of two bits is 1
~	NOT	Inverts all the bits
<<	Zero fill left shift	Shift left by pushing zeros in from the right and let the leftmost bits fall off
>>	Signed right shift	Shift right by pushing copies of the leftmost bit in from the left, and let the rightmost bit

11	Lists	<div>Lists</div> <div><ul style="list-style-type: none">-used to store multiple items in a single variable.- one of 4 built-in data types in Python used to store collections of data, the other 3 are Tuple, Set, and Dictionary, all with different qualities and usage.-are created using square brackets:- items are ordered, changeable, and allow duplicate values.-items are indexed, the first item has index [0], the second item has index [1] etc.- hetrogenious</div> <div><add few more notes from code></div> <div>#list comprehension condition syntax</div> <div>List comprehension offers a shorter syntax when you want to create a new list based on the values of an existing list.</div> <div> </div> <div>newlist = [expression for item in iterable if condition == True]</div> <div>e.g</div> <div>listNew = [item for item in listFruits if "a" in item]</div> <div> </div> <div>#Customize Sort Function</div> <div>You can also customize your own function by using the keyword argument key = function.</div> <div> </div> <div>#Join list - join two list</div> <div>#1. use + operator</div> <div>#2. use append function</div> <div>#3. use extend method</div> <div> </div> <div>List methods</div> <table><tr><th>Method</th><th>Description</th></tr><tr><td>append()</td><td>Adds an element at the end of the list</td></tr><tr><td>clear()</td><td>Removes all the elements from the list</td></tr><tr><td>copy()</td><td>Returns a copy of the list</td></tr><tr><td>count()</td><td>Returns the number of elements with the specified value</td></tr><tr><td>extend()</td><td>Add the elements of a list (or any iterable), to the end of the current list</td></tr><tr><td>index()</td><td>Returns the index of the first element with the specified value</td></tr><tr><td>insert()</td><td>Adds an element at the specified position</td></tr><tr><td>pop()</td><td>Removes the element at the specified position</td></tr><tr><td>remove()</td><td>Removes the item with the specified value</td></tr><tr><td>reverse()</td><td>Reverses the order of the list</td></tr><tr><td>sort()</td><td>Sorts the list</td></tr></table>	Method	Description	append()	Adds an element at the end of the list	clear()	Removes all the elements from the list	copy()	Returns a copy of the list	count()	Returns the number of elements with the specified value	extend()	Add the elements of a list (or any iterable), to the end of the current list	index()	Returns the index of the first element with the specified value	insert()	Adds an element at the specified position	pop()	Removes the element at the specified position	remove()	Removes the item with the specified value	reverse()	Reverses the order of the list	sort()	Sorts the list
Method	Description																									
append()	Adds an element at the end of the list																									
clear()	Removes all the elements from the list																									
copy()	Returns a copy of the list																									
count()	Returns the number of elements with the specified value																									
extend()	Add the elements of a list (or any iterable), to the end of the current list																									
index()	Returns the index of the first element with the specified value																									
insert()	Adds an element at the specified position																									
pop()	Removes the element at the specified position																									
remove()	Removes the item with the specified value																									
reverse()	Reverses the order of the list																									
sort()	Sorts the list																									
12	Tuples	<div>Tuples are used to store multiple items in a single variable. A tuple is a collection which is ordered and unchangeable. hetrogenious</div> <div>Tuples are written with round brackets.</div> <div> </div> <div>#updatetuplevaleus</div>																								

#changetolist,updateandmaketuple

Method	Description
count()	Returns the number of times a specified value occurs in a tuple
index()	Searches the tuple for a specified value and returns the position of where it was found

13

Sets

Sets are used to store multiple items in a single variable.
A set is a collection which is unordered, unchangeable*, and unindexed. duplicates not allowed.

Method	Description
add()	Adds an element to the set
clear()	Removes all the elements from the set
copy()	Returns a copy of the set
difference()	Returns a set containing the difference between two or more sets
difference_update()	Removes the items in this set that are also included in another, specified set
discard()	Remove the specified item
intersection()	Returns a set, that is the intersection of two other sets
intersection_update()	Removes the items in this set that are not present in other, specified set(s)
isdisjoint()	Returns whether two sets have a intersection or not
issubset()	Returns whether another set contains this set or not
issuperset()	Returns whether this set contains another set or not
pop()	Removes an element from the set
remove()	Removes the specified element
symmetric_difference()	Returns a set with the symmetric differences of two sets
symmetric_difference_update()	inserts the symmetric differences from this set and another
union()	Return a set containing the union of sets
update()	Update the set with the union of this set and others

14

Dictionaries

Dictionary
Dictionaries are used to store data values in key:value pairs.
A dictionary is a collection which is ordered*, changeable and do not allow duplicates.
(As of Python version 3.7, dictionaries are ordered. In Python 3.6 and earlier, dictionaries are unordered.)
Dictionaries are written with curly brackets, and have keys and values:
Dictionaries are changeable, meaning that we can change, add or remove items after the dictionary has been created.
The values in dictionary items can be of any data type:

Method	Description
clear()	Removes all the elements from the dictionary
copy()	Returns a copy of the dictionary
fromkeys()	Returns a dictionary with the specified keys and value
get()	Returns the value of the specified key
items()	Returns a list containing a tuple for each key value pair
keys()	Returns a list containing the dictionary's keys
pop()	Removes the element with the specified key

		popitem() Removes the last inserted key-value pair setdefault() Returns the value of the specified key. If the key does not exist: insert the key, with the specified value update() Updates the dictionary with the specified key-value pairs values() Returns a list of all the values in the dictionary
15	If Else	
16	For/While Loop	
17	Function/Lambda function
